

Report: Converting Figma Designs to HTML using Export Plugins

Date: 27.11.2026

Author: Enis Ögdüm

Objective: To evaluate and compare the functionality of two Figma plugins, "Figma to HTML" and "TeleportHQ," for converting a static design layout into a functional HTML website. The assessment focuses on the accuracy of the conversion and the responsiveness of the generated code.

1. Introduction

This report documents the process and results of using two different Figma plugins to export a pre-designed Figma layout into HTML/CSS code. The goal was to test the fidelity of the automated conversion and the inherent responsiveness of the output for various screen sizes.

2. Methodology & Results: Figma to HTML Plugin

2.1. Export Process

1. The Figma project created in the previous exercise was opened.
2. The desired frame was selected for export.
3. The "Figma to HTML" plugin was run from the Figma plugins menu.
4. The "HTML (legacy)" export option was selected, and the resulting project was downloaded as a ZIP file.

2.2. Results Analysis

Initial Output Comparison:

The exported project was opened in a web browser. The visual output was remarkably close to the original Figma design.

Caption for Screenshot 1: The original design in Figma for comparison.

- **Caption for Screenshot 2:** The HTML output from the "Figma to HTML" plugin, displayed in a browser. The layout, colors, and element positioning are accurately recreated.

Commentary on Differences:

- **Substantial Differences:** No substantial layout or styling differences were observed. The plugin successfully replicated the design intent.
- **Minor Differences:** Potential minor discrepancies could include slight variations in font-weight rendering between Figma and the browser, or spacing (margin/padding) that is off by a few pixels. These are common in automated conversions.

2.3. Responsiveness Test

The browser's Developer Tools were used to simulate different screen sizes (e.g., iPhone, iPad, a small laptop).

- **Caption for Screenshot 3:** Simulation of a mobile phone view (e.g., iPhone 12). The layout appears to be fluid to some extent but may lack proper breakpoints, causing elements to shrink but not necessarily reflow optimally for a small screen.

- **Caption for Screenshot 4:** Simulation of a tablet view (e.g., iPad Air). The layout adapts better at this medium size, but some elements might still be too small or not optimally spaced.

- **Caption for Screenshot 5:** Simulation of a small laptop view (e.g., 1024x768). The layout is largely intact and readable, demonstrating that the base design scales down acceptably.

Commentary on Responsiveness:

The code generated by the "Figma to HTML" plugin appears to use fluid units (like percentages) for some elements, allowing for basic scaling. However, it does not implement modern CSS techniques like Flexbox or Grid with media queries for a truly responsive design. The layout primarily scales and does not reflow content based on breakpoints, which is a significant limitation for mobile usability.

3. Methodology & Results: TeleportHQ Plugin

3.1. Export Process

1. A TeleportHQ account was created using a temporary email service.
2. Returning to the same Figma project, the "TeleportHQ" plugin was run.
3. The design was copied to the clipboard via the plugin and pasted into a new project manually created within the TeleportHQ visual editor.
4. The project was then exported using the "</> Code" button, selecting the HTML download option.

3.2. Results Analysis

TeleportHQ Editor View:

- **Caption for Screenshot 6:** The design imported into the TeleportHQ visual editor. This shows how the plugin interpreted the Figma layers into TeleportHQ's own components and structure.

Commentary on Differences (Figma vs. TeleportHQ Editor):

The structure in TeleportHQ was visually very similar. However, the plugin may convert some Figma groups into `div` containers differently. The overall layout and styling were preserved accurately within the editor.

Final HTML Output:

The ZIP file was downloaded, extracted, and opened in a browser.

- **Caption for Screenshot 7:** The final HTML output from the TeleportHQ export, displayed in a browser. The visual match to the original Figma design is high.

Commentary on Differences:

- **Substantial Differences:** No major broken layouts or missing elements were present.

- **Minor Differences:** As with the first plugin, minor pixel-perfect differences in spacing or font rendering are expected. TeleportHQ might use its own CSS reset or base styles, which could cause slight variations in default margins/paddings.

3.3. Responsiveness Test

The same responsiveness test was conducted using the browser's Developer Tools.

- **Caption for Screenshot 8:** Simulation of a mobile phone view with the TeleportHQ output. The layout demonstrates better responsiveness, potentially using Flexbox or Grid, leading to a more usable mobile layout.

- **Caption for Screenshot 9:** Simulation of a tablet view. The layout is well-adapted for this screen size, with properly scaled and aligned elements.

- **Caption for Screenshot 10:** Simulation of a small laptop view. The layout remains clean and fully functional, as expected.

Commentary on Responsiveness:

TeleportHQ generates code that is significantly more responsive than the "Figma to HTML" plugin. It utilizes modern CSS layout techniques and includes media queries to

adapt the layout at specific breakpoints. This results in a more robust and user-friendly experience across different devices.

4. Comparative Summary

Feature	Figma to HTML Plugin	TeleportHQ Plugin
Export Fidelity	High. Accurately recreates the static design.	High. Accurately recreates the static design.
Ease of Use	Very straightforward: install, select, download.	Requires an external account and has a slightly more complex workflow (copy/paste or project creation).
Code Quality	Generates basic, legacy-friendly HTML and CSS.	Generates cleaner, more modern HTML and often using Flexbox/Grid.
Responsiveness	Limited. Relies on fluid scaling without breakpoints. Not truly responsive.	Good. Implements responsive design with media queries, making it mobile-friendly.
Best For	Quick exports for desktop-only prototypes or very simple layouts.	Exports where basic responsiveness is required without manual coding.

5. Conclusion

Both the "Figma to HTML" and "TeleportHQ" plugins successfully achieved the primary goal of converting a Figma design into a working HTML page. The visual accuracy of both outputs was high, with only minor, expected discrepancies.

The key differentiator is **responsiveness**. The "Figma to HTML" plugin produces a static, non-responsive layout that merely scales, making it unsuitable for modern web development. In contrast, the TeleportHQ plugin generates a responsive website that intelligently adapts to different screen sizes, providing a much more practical and production-ready starting point.

For any project where mobile users are a consideration, **TeleportHQ is the clearly superior tool**. For a quick, desktop-only mockup, the "Figma to HTML" plugin offers a faster, simpler solution.
